DEFINITIONS

This card describes POSIX AWK, as well as three freely available awk implementations (see FTP/HTTP/GIT Information). Common extensions (in two or more versions) are printed in light blue. Features specific to just one version—usually GNU AWK (gawk)—are printed in dark blue. Exceptions and deprecated features are printed in red. Features mandated by POSIX are printed in black.

Several type faces are used to clarify the meaning:

- Courier Bold is used for computer input.
- Times Italic is used for emphasis, to indicate user input and for syntactic placeholders, such as variable or action.
- Times Roman is used for explanatory text.

number – a floating point number as in ANSI C, such as 3, 2.3, .4, 1.4e2 or 4.1E5. Numbers may also be given in octal or hexadecimal: e.g., 011 or 0x11.

escape sequences – a special sequence of characters beginning with a backslash, used to describe otherwise unprintable characters. (See Escape Sequences.)

string – a group of characters enclosed in double quotes. Strings may contain escape sequences.

regexp – a regular expression, either a regexp constant enclosed in forward slashes, or a dynamic regexp computed at run-time. Regexp constants may contain escape sequences.

name - a variable, array or function name.

entry(N) – entry entry in section N of the Unix reference manual.

pattern – an expression describing an input record to be matched.

action – statements to execute when an input record is matched.

rule – a pattern-action pair, where the pattern or action may be missing.

COMMAND LINE ARGUMENTS (standard)

Command line arguments control setting the field separator, setting variables before the **BEGIN** rule is run, and the location of AWK program source code. Implementation-specific command line arguments change the behavior of the running interpreter.

-F fs	Use fs for the input field separator.
- v var=val	Assign the value val to the variable var
	before execution of the program begins.
	Such variable values are available to the
	BEGIN rule.
-f prog-file	Read the AWK program source from the file
	prog-file, instead of from the first command
	line argument. Multiple -f options may be
	used.
	Signal the end of options.

BUG REPORTS

If you find a bug in this reference card, please report it via electronic mail to bug-gawk@gnu.org.

COMMAND LINE ARGUMENTS (gawk)

Long options may abbreviated as long as the abbreviation remains unique. You may use "-w option" for full POSIX compliance.

--assign var=val Same as -v.
--field-separator fs Same as -v.
--file prog-file Same as -v.

-b, --characters-as-bytes

Treat all input data as single-byte characters. I.e., don't attempt to process strings as multibyte characters. Overridden by --posix.

-c. --traditional

Disable gawk-specific extensions.

-C, --copyright

Print the short version of the GNU copyright information on **stdout**.

-d[file], --dump-variables[=file]

Print a sorted list of global variables, their types and final values to *file* (default: awkvars.out).

-D[file], --debug[=file]

Enable debugging of program. Optionally read stored commands from file.

-e 'text', --source 'text'

Use text as AWK program source code.

-E file, --exec file

Read program text from *file*. No other options are processed. Also disable command-line variable assignments. Useful with #!.

-g, --gen-pot

Process the program and print a GNU **gettext** format .pot file on **stdout**, containing the text of all strings that were marked for localization.

-h, --help

Print a short summary of the available options on **stdout**, then exit zero.

-i file, --include file

Include library AWK code in file.

-1 lib, --load lib

Load dynamic extension lib.

-L [value], --lint[=value]

Warn about dubious or non-portable constructs. If *value* is **fatal**, lint warnings become fatal errors. If *value* is **invalid**, only issue warnings about things that are actually invalid (not fully implemented yet).

-M, --bignum

Enable arbitrary-precision arithmetic.

-n, --non-decimal-data

Recognize octal and hexadecimal values in input data. Use this option with great caution!

-N,--use-lc-numeric

Force use of the locale's decimal point character when parsing input data.

-o[file], --pretty-print[=file]

Output a pretty printed version of the program to *file* (default: awkprof.out).

-O, --optimize

Enable some internal optimizations.

$-{\tt p}[\mathit{file}], --{\tt profile}[\mathit{=file}]$

Send profiling data to *file* (default: **awkprof.out**). The profile contains execution counts in the left margin of each statement in the program.

-P, --posix

Disable common and GNU extensions.

COMMAND LINE ARGUMENTS (gawk)

-r, --re-interval

Enable interval expressions. (Needed with -c.)

-S. --sandbox

Disable the **system()** function, input redirection with **getline**, output redirection with **print** and **printf**, and loading dynamic extensions.

-t. --lint-old

Warn about constructs that are not portable to the original version of Unix awk.

-V, --version

Print version info on stdout and exit zero.

Normally, if there is program text, unknown options are passed on to the AWK program in **ARGV** for processing. In compatibility mode, unknown options are flagged as invalid, but are otherwise ignored.

COMMAND LINE ARGUMENTS (mawk)

The following options are specific to mawk.

-W dump Print an assembly listing of the program to stdout and exit zero. -W exec file Read program text from file. No other options are processed. Useful with #!. -W interactive Unbuffer stdout and line buffer stdin. Lines are always records, ignoring RS. -W posix_space \n separates fields when RS = "". -W sprintf=num Adjust the size of mawk's internal sprintf buffer. -W version Print version and copyright on

The options may be abbreviated using just the first letter, e.g. -We, -Wv and so on.

stderr, and exit zero.

stdout. limit information

SIGNALS (gawk --profile).

gawk accepts two signals while profiling. SIGUSR1 dumps a profile and function call stack to the profile file. It then continues to run. SIGHUP is similar, but exits.

LINES AND STATEMENTS

AWK is a line-oriented language. The pattern comes first, and then the action. Action statements are enclosed in { and }. Either the pattern or the action may be missing, but not both. If the pattern is missing, the action is executed for every input record. A missing action is equivalent to

{ print }

which prints the entire record.

Comments begin with the # character, and continue until the end of the line. Normally, statements end with a newline, but lines ending in a ",", {, ?, :, &&, or | |, are automatically continued. Lines ending in do or else also have their statements automatically continued on the following line. In other cases, a line can be continued by ending it with a "\", in which case the newline is ignored. However, a "\" after a # is not special.

Multiple statements may be put on one line by separating them with a ";". This applies to both the statements within the action part of a pattern-action pair (the usual case) and to the pattern-action statements themselves.

3

AWK PROGRAM EXECUTION

AWK programs are a sequence of pattern-action statements and optional function definitions.

```
@include "filename"
@load "filename"
pattern { action statements }
function name(parameter list) { statements }
```

awk first reads the program source from the prog-file(s), if specified, from arguments to --source, or from the first non-option argument on the command line. The program text is read as if all the prog-file(s) and command line source texts had been concatenated.

gawk includes files named on @include lines. Nested includes are allowed. gawk loads extensions named on @load lines; see Dynamic Extensions.

AWK programs execute in the following order. First, all variable assignments specified via the -v option are performed. Next, awk executes the code in the BEGIN rules(s), if any, and then proceeds to read the files 1 through ARGC - 1 in the ARGV array. If there are no files named on the command line, awk reads the standard input.

A command line argument of the form var=val, is treated as a variable assignment. The variable var is assigned the value val. (This happens after any **BEGIN** rule(s) have been run.) Command line variable assignment is most useful for dynamically assigning values to the variables **awk** uses to control how input is broken into fields and records. It is also useful for controlling state if multiple passes are needed over a single data file.

If the value of a particular element of ARGV is empty (""), awk skips over it.

For each input file, if a **BEGINFILE** rule exists, **gawk** executes the associated code before processing the contents of the file. Similarly, **gawk** executes the code associated with **ENDFILE** after processing the file.

For each record in the input, **awk** tests to see if it matches any *pattern* in the AWK program. For each pattern that the record matches, the associated *action* is executed. The patterns are tested in the order they occur in the program.

Finally, after all the input is exhausted, **awk** executes the code in the **END** rule(s), if any.

If a program only has a **BEGIN** rule, no input files are processed. If a program only has an **END** rule, the input is read.

_____VARIABLES _____ Number of command line arguments.

ARGC

	Transcer of communic into arguments	
ARGIND	Index in ARGV of current data file.	
ARGV	Array of command line arguments. Indexed from 0	
	to ARGC - 1. Dynamically changing the contents	
	of ARGV can control the files used for data.	
BINMODE	Controls "binary" mode for all file I/O. Values of	
	1, 2, or 3, indicate input, output, or all files,	
	respectively, should use binary I/O. (Not Brian	
	Kernighan's awk.) Applies only to non-POSIX	
	systems. For gawk, string values of "r", or "w"	
	specify that input files, or output files, respectively,	
	should use binary I/O. Use "rw" or "wr" for all	
	files.	

_VARIABLES (continued)

VAI	RIABLES (continued)
CONVFMT	Conversion format for numbers, default value is "%.6g".
ENVIRON	Array containing the current environment. It is indexed by the environment variable names, each element being the value of that variable.
ERRNO	String error value if a getline redirection or read fails, or if close() fails.
FIELDWIDTHS	Whitespace separated list of field widths. Used to parse the input into fields of fixed width, instead of the value of FS.
FILENAME	Name of the current input file. If no files given on the command line, FILENAME is "—". FILENAME is undefined inside the
	BEGIN rule (unless set by getline).
FNR	Record number in current input file.
FPAT	Regular expression describing field contents. Used to parse the input based on the fields
	instead of the field separator.
FS	Input field separator, a space by default (see Fields).
FUNCTAB	An array indexed by the names of all user-
IGNORECASE	defined and extension functions. If non-zero, all regular expression and string operations ignore case. Array subscripting is <i>not</i> affected. However, the asort() and
LINT	asorti() function are affected. Provides dynamic control of thelint option from within an AWK program.
NF	Number of fields in the current input record.
NR OFMT	Total number of input records seen so far. Output format for numbers, "%.6g", by
OFMI	default.
OFS	Output field separator, a space by default.
ORS	Output record separator, a newline by default.
PREC	The working precision of arbitrary precision floating-point numbers, 53 by default.
PROCINFO	Elements of this array provide access to information about the running AWK program. See <i>GAWK: Effective AWK Programming</i> for details.
RLENGTH	Length of the string matched by match(); -1 if no match.
ROUNDMODE	The rounding mode to use for arbitrary precision arithmetic, by default "N".
RS	Input record separator, a newline by default (see Records).
RSTART	Index of the first character matched by match(); 0 if no match.
RT	Record terminator. gawk sets RT to the input text that matched the character or
SUBSEP	regular expression specified by RS. Character(s) used to separate multiple subscripts in array elements, by default "\034". (See Arrays).
SYMTAB	An array indexed by the names of all global variables and arrays. May be used to
TEXTDOMAIN	indirectly set variable and array values. The internationalization text domain, for finding the localized translations of the program's strings.

6

ARRAYS

An array subscript is an expression between square brackets ([and]). If the expression is a list (expr, expr ...), then the subscript is a string consisting of the concatenation of the (string) value of each expression, separated by the value of SUBSEP. This simulates multi-dimensional arrays. For example:

```
i = "A"; j = "B"; k = "C"
x[i, j, k] = "hello, world\n"
```

assigns "hello, world\n" to the element of the array x indexed by the string "A\034B\034C". All arrays in AWK are associative, i.e., indexed by string values.

Use the special operator in in an if or while statement to see if a particular value is an array index.

```
if (val in array)
    print array[val]
```

If the array has multiple subscripts, use (i, j) in array.

Use the in construct in a for loop to iterate over all the elements of an array.

Use the **delete** statement to delete an element from an array. Specifying just the array name without a subscript in the **delete** statement deletes the entire contents of an array. You cannot use **delete** with **FUNCTAB** or **SYMTAB**.

gawk provides true multidimensional arrays. Such arrays need not be "rectangular" as in C or C++. For example:

```
a[1] = 5; a[2][1] = 6; a[2][2] = 7
```

EXPRESSIONS

Expressions are used as patterns, for controlling conditional action statements, and to produce parameter values when calling functions. Expressions may also be used as simple statements, particularly if they have side-effects such as assignment. Expressions mix *operands* and *operators*. Operands are constants, fields, variables, array elements, and the return values from function calls (both built-in and user-defined).

Regexp constants (/pat/), when used as simple expressions, i.e., not used on the right-hand side of ~ and !~, or as arguments to the gensub(), gsub(), match(), patsplit(), split(), and sub(), functions, mean \$0 ~ /pat/.

The AWK operators, in order of decreasing precedence, are:

()	Grouping
\$	Field reference
++	Increment and decrement, prefix and postfix
^ **	Exponentiation
+ - !	Unary plus, unary minus, and logical negation
* / %	Multiplication, division, and modulus
+ -	Addition and subtraction
space	String concatenation
< >	Less than, greater than
<= >=	Less than or equal, greater than or equal
!= ==	Not equal, equal
~ !~	Regular expression match, negated match
in	Array membership
&&	Logical AND, short circuit
	Logical OR, short circuit
?:	In-line conditional expression
= += -= *= /=	* %= ^= **=
	Assignment operators

CONVERSIONS AND COMPARISONS

Variables and fields may be (floating point) numbers, strings or both. Context determines how a variable's value is interpreted. If used in a numeric expression, it will be treated as a number, if used as a string it will be treated as a string.

To force a variable to be treated as a number, add 0 to it; to force it to be treated as a string, concatenate it with the null string.

Uninitialized variables have the numeric value 0 and the string value "" (the null, or empty, string).

When a string must be converted to a number, the conversion is accomplished using *strtod*(3). A number is converted to a string by using the value of **CONVFMT** as a format string for *sprintf*(3), with the numeric value of the variable as the argument. However, even though all numbers in AWK are floating-point, integral values are *always* converted as integers.

Comparisons are performed as follows: If two variables are numeric, they are compared numerically. If one value is numeric and the other has a string value that is a "numeric string," then comparisons are also done numerically. Otherwise, the numeric value is converted to a string, and a string comparison is performed. Two strings are compared, of course, as strings.

Note that string constants, such as "57", are not numeric strings, they are string constants. The idea of "numeric string" only applies to fields, getline input, FILENAME, ARGV elements, ENVIRON elements and the elements of an array created by split() or patsplit() that are numeric strings. The basic idea is that user input, and only user input, that looks numeric, should be treated that way.

PATTERN ELEMENTS

AWK patterns may be one of the following.

BEGIN END BEGINFILE ENDFILE expression pat1, pat2

BEGIN and **END** are special patterns that provide start-up and clean-up actions respectively. They must have actions. There can be multiple **BEGIN** and **END** rules; they are merged and executed as if there had just been one large rule. They may occur anywhere in a program, including different source files.

BEGINFILE and ENDFILE are special patterns that execute before the first record of each file and after the last record of each file, respectively. In the BEGINFILE rule, the ERRNO variable is non-null if there is a problem with the file; the rule should use nextfile to skip the file if desired. Otherwise gawk exits with its usual fatal error. The actions for multiple BEGINFILE and ENDFILE patterns are merged.

Expression patterns can be any expression, as described under Expressions.

The *pat1*, *pat2* pattern is called a *range pattern*. It matches all input records starting with a record that matches *pat1*, and continuing until a record that matches *pat2*, inclusive. It does not combine with any other pattern expression.

.

ACTION STATEMENTS

break

Break out of the nearest enclosing switch statement, or do, for, or while loop.

continue

Skip the rest of the loop body. Evaluate the *condition* part of the nearest enclosing **do** or **while** loop, or go to the *incr* part of a **for** loop.

delete array[index]

Delete element *index* from array *array*.

delete array

Delete all elements from array array.

do statement while (condition)

Execute *statement* while *condition* is true. The *statement* is always executed at least once.

exit[expression]

Terminate input record processing. Execute the **END** rule(s) if present. If present, *expression* becomes **awk**'s return value.

for (init; cond; incr) statement

Execute *init*. Evaluate *cond*. If it is true, execute *statement*. Execute *incr* before going back to the top to re-evaluate *cond*. Any of the three may be omitted. A missing *cond* is considered to be true.

for (var in array) statement

Execute *statement* once for each subscript in *array*, with *var* set to a different subscript each time through the loop.

if (condition) statement1 [else statement2]

If *condition* is true, execute *statement1*, otherwise execute *statement2*. Each **else** matches the closest **if**.

Switch on *expression*, execute *case* if matched, default if not. The **default** label and associated statements are optional.

while (condition) statement

While condition is true, execute statement.

{ statements }

A list of statements enclosed in braces can be used anywhere that a single statement would otherwise be used.

ESCAPE SEQUENCES

Within strings constants ("...") and regexp constants (/.../), escape sequences may be used to generate otherwise unprintable characters. This table lists the available escape sequences.

\a	alert (bell)	\r	carriage return
\b	backspace	\t	horizontal tab
\ f	form feed	\v	vertical tab
\n	newline	\\	backslash
\d	octal value ddd	$\mathbf{x}hh$	hex value hh
\ "	double quote	\/	forward slash

RECORDS

Normally, records are separated by newline characters. Assigning values to the built-in variable RS controls how records are separated. If RS is any single character, that character separates records. Otherwise, RS is a regular expression. (Not Brian Kernighan's awk.) Text in the input that matches this regular expression separates the record. gawk sets RT to the value of the input text that matched the regular expression. The value of IGNORECASE also affects how records are separated when RS is a regular expression. If RS is set to the null string, then records are separated by one or more blank lines. When RS is set to the null string, the newline character always acts as a field separator, in addition to whatever value FS may have. mawk does not apply exceptional rules to FS when RS = "".

FIELDS

As each input record is read, **awk** splits the record into *fields*, using the value of the **FS** variable as the field separator. If **FS** is a single character, fields are separated by that character. If **FS** is the null string, then each individual character becomes a separate field. Otherwise, **FS** is expected to be a full regular expression. In the special case that **FS** is a single space, fields are separated by runs of spaces and/or tabs and/or newlines. Leading and trailing whitespace are ignored. The value of **IGNORECASE** also affects how fields are split when **FS** is a regular expression.

If the **FIELDWIDTHS** variable is set to a space-separated list of numbers, each field is expected to have a fixed width, and **gawk** splits up the record using the specified widths. The value of **FS** is ignored. Assigning a new value to **FS** or **FPAT** overrides the use of **FIELDWIDTHS**. and restores the default behavior.

Similarly, if the **FPAT** variable is set to a string representing a regular expression, each field is made up of text that matches that regular expression. In this case, the regular expression describes the fields themselves, instead of the text that separates the fields. Assigning a new value to **FS** or **FIELDWIDTHS** overrides the use of **FPAT**.

Each field in the input record may be referenced by its position: \$1, \$2 and so on. \$0 is the whole record. Fields may also be assigned new values.

The variable **NF** is set to the total number of fields in the input record.

References to non-existent fields (i.e., fields after \$NF) produce the null string. However, assigning to a non-existent field (e.g., \$(NF+2) = 5) increases the value of NF, creates any intervening fields with the null string as their value, and causes the value of \$0 to be recomputed with the fields being separated by the value of OFS. References to negative numbered fields cause a fatal error. Decreasing the value of NF causes the trailing fields to be lost (not Brian Kernighan's awk).

HISTORICAL FEATURES (gawk)

It is possible to call the length() built-in function not only with no argument, but even without parentheses. Doing so, however, is poor practice, and gawk issues a warning about its use if --lint is specified on the command line.

REGULAR EXPRESSIONS

Regular expressions are the extended kind originally defined by egrep. gawk supports additional GNU operators. A word-constituent character is a letter, digit, or underscore (_).

	Summary of Regular Expressions
	In Decreasing Precedence
(r)	regular expression (for grouping)
c	if non-special character, matches itself
$\backslash c$	turn off special meaning of c
^	beginning of string (note: <i>not</i> line)
\$	end of string (note: <i>not</i> line)
•	any single character, including newline
[]	any one character in or range
[^]	any one character not in or range
\ y	word boundary
\B	middle of a word
\<	beginning of a word
\>	end of a word
\s	any whitespace character
\S	any non-whitespace character
\w	any word-constituent character
\W	any non-word-constituent character
\ 1	beginning of a string
\'	end of a string
r*	zero or more occurrences of r
r+	one or more occurrences of r
r?	zero or one occurrences of r
$r\{n,m\}$	n to m occurrences of r (POSIX: see note below)
$r\dot{l} \mid r2$	r1 or r2

The $r\{n,m\}$ notation is called an *interval expression*. Not supported by mawk or Brian Kernighan's awk.

In regular expressions, within character ranges ([...]), the notation [[:class:]] defines character classes:

alnum	alphanumeric	lower	lowercase
alpha	alphabetic	print	printable
blank	space or tab	punct	punctuation
cntrl	control	space	whitespace
digit	decimal	upper	uppercase
graph	non-spaces	xdigit	hexadecimal

ENVIRONMENT VARIABLES (gawk)

The environment variable AWKPATH specifies a search path to use when finding source files named with the -f option. The default path is ".:/usr/local/share/awk". If a file name given to the -f option contains a "/" character, no path search is performed.

The variable AWKLIBPATH specifies the search path for dynamic extensions to use with @load and the -l option.

For socket communication, **GAWK_SOCK_RETRIES** controls the number of connection retries, and **GAWK_MSEC_SLEEP** controls the interval between retries. The interval is in milliseconds. On systems that do not support *usleep*(3), the value is rounded up to an integral number of seconds.

The value of GAWK_READ_TIMEOUT specifies the time, in milliseconds, for gawk to wait for input before returning with an error

If POSIXLY_CORRECT exists then gawk behaves exactly as if the --posix option had been given.

LOCALIZATION (gawk)

There are several steps involved in producing and running a localizable **awk** program.

 Add a BEGIN action to assign a value to the TEXTDOMAIN variable to set the text domain for your program.

```
BEGIN { TEXTDOMAIN = "myprog" }
```

This allows gawk to find the .gmo file associated with your program. Without this step, gawk uses the messages text domain, which probably won't work.

- 2. Mark all strings that should be translated with leading underscores
- 3. Use the **bindtextdomain()**, **dcgettext()**, and/or **dcngettext()** functions in your program, as appropriate.
- 1 Dun

```
gawk --gen-pot -f myprog.awk > myprog.pot
to generate a .pot file for your program.
```

5. Provide appropriate translations, and build and install a corresponding **.gmo** file.

The internationalization features are described in full detail in GAWK: Effective AWK Programming.

SPECIAL FILENAMES

All three **awk** implementations recognize certain special filenames internally when doing I/O redirection from either **print** or **printf** into a file or via **getline** from a file. These filenames provide access to open file descriptors inherited from the parent process. They may also be used on the command line to name data files. The filenames are:

```
"-" standard input
/dev/stdin standard input
/dev/stdout standard output
/dev/stderr standard error output
```

The following names are specific to gawk.

/dev/fd/n

File associated with the open file descriptor n.

/inet/tcp/lport/rhost/rport

/inet4/tcp/lport/rhost/rport

/inet6/tcp/lport/rhost/rport

Files for TCP/IP connections on local port *lport* to remote host *rhost* on remote port *rport*. Use a port of 0 to have the system pick a port. Use /inet4 to force an IPv4 connection, and /inet6 to force an IPv6 connection. Plain /inet uses the system default (probably IPv4). Usable only with the |& two-way I/O operator.

/inet/udp/lport/rhost/rport

/inet4/udp/lport/rhost/rport

/inet6/udp/lport/rhost/rport

Similar, but use UDP/IP instead of TCP/IP.

.

INPUT CONTROL

getline		Set \$0 from next record; set NF, NR,			
		FNR.			
	getline < file	Set \$0 from next record of <i>file</i> ; set NF .			
	getline v	Set v from next input record; set NR,			
		FNR.			
	getline v < file	Set v from next record of file.			
	cmd getline	Pipe into getline; set \$0, NF.			
	cmd getline v	Pipe into getline ; set v.			
	cmd & getline				
	Co-process pipe into	getline; set \$0, NF.			
	cmd & getline v				
	Co-process pipe into	getline; set v.			
	next				

Stop processing the current input record. Read next input record and start over with the first pattern in the program. Upon end of the input data, execute any END rule(s).

nextfile

Stop processing the current input file. The next input record comes from the next input file. Update FILENAME and ARGIND, reset FNR to 1, and start over with the first pattern. Upon end of input data, execute any END rule(s).

getline returns 1 on success, 0 on end of file, and -1 on an error. All versions set RT. Upon an error, ERRNO contains a string describing the problem.

OUTPUT CONTROL

fflush([file])

Flush any buffers associated with the open output file or pipe file. If no file, or if file is null, then flush all open output files and pipes.

Print the current record. Terminate output record with ORS. print expr-list

Print expressions. Each expression is separated by the value of OFS. Terminate the output record with ORS.

printf fmt, expr-list

Format and print (see Printf Formats).

system(cmd)

Execute the command *cmd*, and return the exit status (may not be available on non-POSIX systems).

I/O redirections may be used with both print and printf.

print "hello" > file

Print data to file. The first time the file is written to, it is truncated. Subsequent commands append data.

print "hello" >> file

Append data to file. The previous contents of file are not lost.

print "hello" | cmd

Print data down a pipeline to cmd.

print "hello" & cmd

Print data down a pipeline to co-process cmd.

CLOSING REDIRECTIONS

close(file)

Close input or output file, pipe or co-process.

close(command, how)

Close one end of co-process pipe. Use "to" for the write end, or "from" for the read end.

On success, close() returns zero for a file, or the exit status for a process. It returns -1 if file was never opened, or if there was a system problem. ERRNO describes the error.

PRINTF FORMATS

The printf statement and sprintf() function accept the following conversion specification formats:

%C	An ASCII character
%d,%i	A decimal number (the integer part)
% e	A floating point number of the form
	[-]d.dddddde[+-]dd
%E	Like %e, but use E instead of e
%£	A floating point number of the form
	[-]ddd.ddddd
% F	Like %f, but use capital letters for infinity and
	not-a-number values.
%g	Use %e or %f, whichever is shorter, with
	nonsignificant zeros suppressed
%G	Like %g, but use %E instead of %e
%o	An unsigned octal integer
%u	An unsigned decimal integer
%s	A character string
% x	An unsigned hexadecimal integer
%X	Like %x, but use ABCDEF for 10–15
%%	A literal %; no argument is converted

Optional, additional parameters may lie between the % and the

control letter:	
count\$	Use the <i>count</i> 'th argument at this point in the formatting (a <i>positional specifier</i>). Use in translated versions of format strings, not in the original text of an AWK program.
-	Left-justify the expression within its field.
space	For numeric conversions, prefix positive values with a space and negative values with a minus sign.
+	Use before the <i>width</i> modifier to always supply a sign for numeric conversions, even if the data to be formatted is positive. The + overrides the space modifier.
#	Use an "alternate form" for some control letters:
%0	Supply a leading zero.
%x, %X	Supply a leading 0x or 0x for a nonzero result.
%e, %E, %f	The result always has a decimal point.

%g, %G Trailing zeros are not removed. Pad output with zeros instead of spaces. This applies only to the numeric output formats. Only

has an effect when the field width is wider than the value to be printed.

Use the locale's thousands separator for %d, %i and %u.

width Pad the field to this width. The field is normally padded with spaces. If the 0 flag has been used, pad with zeros.

• prec Precision. The meaning of the prec varies by control letter:

%d,%o,%i,

Λ

%u, %x, %X The minimum number of digits to print. %e, %E, %f The number of digits to print to the right of the

decimal point.

The maximum number of significant digits. %g, %G %s The maximum number of characters to print.

Use a * in place of either the width or prec specifications to take their values from the printf or sprintf() argument list. Use *n\$ to use positional specifiers with a dynamic width or precision.

USER-DEFINED FUNCTIONS

Functions in AWK are defined as follows:

Functions are executed when they are called from within expressions in either patterns or actions. Actual parameters supplied in the function call instantiate the formal parameters declared in the function. Arrays are passed by reference, other variables are passed by value.

Local variables are declared as extra parameters in the parameter list. The convention is to separate local variables from real parameters by extra spaces in the parameter list. For example:

The left parenthesis in a function call is required to immediately follow the function name without any intervening whitespace. This is to avoid a syntactic ambiguity with the concatenation operator. This restriction does not apply to the built-in functions.

Functions may call each other and may be recursive. Function parameters used as local variables are initialized to the null string and the number zero upon function invocation.

Functions may be called indirectly. To do this, assign the name of the function to be called, as a string, to a variable. Then use the variable as if it were the name of a function, prefixed with an "at" sign, like so:

Use **return** to return a value from a function. The return value is undefined if no value is provided, or if the function returns by "falling off" the end.

The word func may be used in place of function. This usage is deprecated.

NUMERIC FUNCTIONS

```
atan2(y, x)
                    The arctangent of y/x in radians.
cos(expr)
                    The cosine of expr, which is in radians.
exp(expr)
                    The exponential function (e \hat{x}).
int(expr)
                    Truncate to integer.
                    The natural logarithm function (base e).
log(expr)
rand()
                    A random number N such that 0 \le N < 1.
sin(expr)
                    The sine of expr, which is in radians.
sqrt(expr)
                    The square root of expr.
srand([expr])
                    Use expr as the new seed for the random
                    number generator. If no expr, use the time of
                    day. Return the previous seed.
```

15

STRING FUNCTIONS

asort(s[, d[, comp]])

Sort the source array s, replacing the indices with numeric values 1 through n (the number of elements in the array), and return the number of elements. If destination d is supplied, copy s to d, sort d, and leave s unchanged. Use comp to compare indices and elements.

asorti(s[, d[, comp]])

Like asort(), but sort on the indices, not the values. The original values are thrown array, so provide a second array to preserve the first.

gensub(r, s, h[, t])

Search the target string t for matches of the regular expression r. If h is a string beginning with g or G, replace all matches of r with s. Otherwise, h is a number indicating which match of r to replace. If t is not supplied, use \$0 instead. Within the replacement text s, the sequence \n , where n is a digit from 1 to 9, may be used to indicate just the text that matched the nth parenthesized subexpression. The sequence \n 0 represents the entire matched text, as does the character &. Unlike sub() and gsub(), the modified string is returned as the result of the function, and the original target string is not changed.

gsub(r, s[, t])

For each substring matching the regular expression r in the string t, substitute the string s, and return the number of substitutions. If t is not supplied, use 0. An t in the replacement text is replaced with the text that was actually matched. Use t to get a literal t. See t See

index(s, t)

Return the index of the string t in the string s, or 0 if t is not present.

length([s])

Return the length of the string s, or the length of \$0 if s is not supplied. With an array argument, return the number of elements in the array.

match(s, r[, a])

Return the position in s where the regular expression r occurs, or 0 if r is not present, and set the values of variables RSTART and RLENGTH. If a is supplied, the text matching all of r is placed in a[0]. If there were parenthesized subexpressions, the matching texts are placed in a[1], a[2], and so on. Subscripts a[n, "start"], and a[n, "length"] provide the starting index in the string and length, respectively, of each matching substring.

patsplit(s, a[, r[, seps]])

Split the string s into the array a and the array seps of separator strings using the regular expression r, and return the number of fields. Element values are the portions of s that matched r. The value of seps[i] is the separator that appeared in front of a[i+1]. If r is omitted, use **FPAT** instead. Clear the arrays a and seps first. Splitting behaves identically to field splitting with **FPAT**.

split(s, a[, r[, seps]])

Split the string s into the array a and the array seps of separator strings using the regular expression r, and return the number of fields. If r is omitted, use FS instead. Clear the a and seps first. Splitting behaves identically to field splitting. (See Fields.)

sprintf(fmt, expr-list)

Print *expr-list* according to *fmt*, and return the result.

STRING FUNCTIONS (continued)

strtonum(s)

Examine s, and return its numeric value. If s begins with a leading $\mathbf{0}$, treat it as an octal number. If s begins with a leading $\mathbf{0}\mathbf{x}$ or $\mathbf{0}\mathbf{x}$, treat s as a hexadecimal number. Otherwise, treat the number as decimal.

sub(r, s[, t])

Just like <code>gsub()</code>, but replace only the first matching substring.

substr(s, i[, n])

Return the at most n-character substring of s starting at i. If n is omitted, use the rest of s.

tolower(str)

Return a copy of the string *str*, with all the uppercase characters in *str* translated to their corresponding lowercase counterparts. Non-alphabetic characters are left unchanged.

toupper(str)

Return a copy of the string *str*, with all the lowercase characters in *str* translated to their corresponding uppercase counterparts. Non-alphabetic characters are left unchanged.

TIME FUNCTIONS

gawk and mawk provide the following functions for obtaining time stamps and formatting them.

mktime(datespec)

Convert *datespec* into a time stamp of the same form as returned by **systime()** and return it. The *datespec* is a string of the form "YYYY MM DD HH MM SS[DST]".

strftime([format[, timestamp[, utc-flag]]])

Format timestamp according to the specification in format. The timestamp should be of the same form as returned by systime(). If utc-flag is present and is non-zero or non-null, the result is in UTC, otherwise it is in local time. If timestamp is missing, use the current time of day. If format is missing, use PROCINFO["strftime"]. The default value is equivalent to the output of date(1).

systime()

Return the current time of day as the number of seconds since the Epoch.

BIT MANIPULATION FUNCTIONS (gawk)

gawk provides the following bit manipulation functions.

and(v1, v2[, ...])

Return the bitwise AND of the arguments.

compl(val)

Return the bitwise complement of *val*.

lshift(val, count)

Return the value of val, shifted left by count bits.

or(v1, v2[,...])

Return the bitwise OR of the arguments.

rshift(val, count)

Return the value of val, shifted right by count bits.

xor(v1, v2[, ...])

Return the bitwise XOR of the arguments.

DYNAMIC EXTENSIONS (gawk)

@load "extension"

Dynamically load the named *extension*. This adds new builtin functions to **gawk**. The extension is loaded during the parsing of the program. See the manual for details.

TYPE FUNCTIONS (gawk)

isarray(x)

Return true if x is an array, false otherwise.

_INTERNATIONALIZATION (gawk).

gawk provides the following functions for runtime message translation.

bindtextdomain(directory[, domain])

Specify the directory where **gawk** looks for the **.gmo** files, in case they will not or cannot be placed in the "standard" locations (e.g., during testing). Return the directory where *domain* is "bound."

The default *domain* is the value of **TEXTDOMAIN**. When *directory* is the null string (""), **bindtextdomain()** returns the current binding for the given *domain*.

dcgettext(string[, domain[, category]])

Return the translation of *string* in text domain *domain* for locale category *category*. The default value for *domain* is the current value of **TEXTDOMAIN**. The default value for *category* is "LC_MESSAGES".

If you supply a value for *category*, it must be a string equal to one of the known locale categories. You must also supply a text domain. Use **TEXTDOMAIN** to use the current domain.

dcngettext(string1, string2, number[, dom[, cat]])
 Return the plural form used for number of the translation of
 string1 and string2 in text domain dom for locale category
 cat. The default value for dom is the current value of
 TEXTDOMAIN. The default for "LC_MESSAGES" is cat.

If you supply a value for *cat*, it must be a string equal to one of the known locale categories. You must also supply a text domain. Use **TEXTDOMAIN** to use the current domain.

FTP/HTTP/GIT INFORMATION

Host: ftp.gnu.org

File: /gnu/gawk/gawk-4.1.0.tar.gz

GNU awk (gawk). There may be a later version.

git clone git://github.com/onetrueawk/awk
Brian Kernighan's awk. This version requires an ANSI C compiler; GCC (the GNU Compiler Collection) works well.

Host: invisible-island.net

File: /mawk/mawk.tar.gz

Michael Brennan's mawk. Thomas Dickey now maintains it.
